Keywords:	Sound Art Installation, Documentation, Spatial Audio Recording
Abstract:	The documentation of sound art installation has received scant research attention. This paper investigates the sensory experience of spatial audio recordings of two sound art installations: Écosystème(s) by Estelle Schorpp and Générateur Stochastique by Jean-Pierre Gauthier. We conducted interactive listening sessions with participants from different fields of expertise: sound artists; sound engineers; new media and sound art curators; and new media and sound art conservators. Listening sessions were followed by semi-structured interviews questioning the selection of significant positions in time and space in the recordings. The analysis revealed a broad range of listening strategies which expand the literature on documentation frameworks. This research shows the potential for methodologically including the sensory experience in the documentation of sound art installations and discusses the use of spatial recording as a tool for the specification of documentation in a multi-expertise context.

Introduction

Time-based and technology-based installation art as long been questioned in terms of conservation (see Real, 2001 for a summary), but the documentation and conservation of sound art installation has however received much less research attention. The handful of studies on sound art installation include Bressan & Canazza (2014), Lacey (2016), Stokowy (2017), Nakagawa & Kaneko (2017), Vasquez (2019), and Fraisse *et al.* (2022) from historical, sociological and technical perspectives, respectively. In terms of actual documentation practice, Brost (2018) published an extensive framework from a museum studies perspective for sound in time-based media installations, “from the artist’s vision for the listener experience of the artwork to its realization in the exhibition space”. She builds notably upon Philipps’ (2015) distinction between the documentation of the artwork (the identity report) and of a single installation (the iteration report), reminding us that “documentation is a primary conservation strategy for time-based media artworks. [...] Unlike artworks in traditional media, time-based media works only exist when they are installed”. A telling example is provided by Eppley (2017), discussing outdoor reinstallation and impact of neighborhood’s modifications for Max Neuhaus’ famous *Times Square* (1977) piece: “[...] one might assess how the new seating arrangement affects acoustic perception, or if its tones need to be ‘retuned’ to a new material density [...]”. In Brost’s framework though, the listener experience is scantily described, limited to broad documentation categories, namely *ideal listener experience*, *additional listener experiences*, and *subjective listener experience*. During the project Sound Art Documentation: Spatial Audio and Significant Knowledge (SAD – SASK), we investigated the relation between sound art installations, documentation practice and the sensory experience of a sound artwork. In the first part of the project, we developed a technical description framework for sound art installation in Quebec based on the literature and a review of the artistic practices (see Fraisse *et al.* 2022). Based on this framework, we selected two sound art installations (see

Boutard et al. 2022) for the second part of the project, which focuses on the sensory experience in relation to documentation. The present paper discusses the outcomes of this second part.

This next phase started with spatial audio recordings of two sound art installations: Estelle Schorpp's *Écosystème(s)* (see Schorpp 2019); and Jean-Pierre Gauthier's *Générateur Stochastique* (see OBORO, 2020). McConchie (2018) proposed to use virtual reality tools for documentation purposes but little has been done for sound art, as compared to the use of virtualization for access projects in the same artistic domain, for example Sporobole's (2023) *Déjà-Vu* platform. The distinction is important as the project consciously does not include a visual immersive rendition but concentrates on spatial audio rendering to investigate sound art installation documentation. Bandt (2006), for example, defined sound installations as "a sonic intermedia practice, which blurs the boundaries of the visual and aural and includes the spatial, the temporal and the haptic". There is thus a strong reduction of the idea of sensory experience proposed in this project for the sake of the research. Furthermore, this study aims at questioning the relation between documentation and the sensory experience from a multi-expertise perspective, including sound artists (SA), sound engineers (SE), new media and sound art curators (CU); and new media and sound art conservators (CO).

By confronting various fields of expertise to spatial audio documentation we propose to discuss strategies guiding the sensory experience and its relation to documentation and the literature in these fields. Building on Boutard and Guastavino's (2012) notion of significant knowledge – based on the inclusion of tacit knowledge into explicit knowledge-driven documentation frameworks – we will further discuss the role of spatial audio documentation tools for documentation frameworks.

Methodology

Spatial audio recordings

Estelle Schorpp's *Écosystème(s)* was recorded on March 12th 2021 in the Centre for Interdisciplinary Research in Music Media and Technology's (CIRMMT) MultiMedia Room (MMR) at McGill University in Montréal, where it was installed by the artist for the purpose of this research. Jean-Pierre Gauthier's *Générateur stochastique* was recorded on June 14th 2021, at gallery Ellephant in Montréal, where it was on exhibition, but outside visiting hours. The spatial audio recordings were conducted using a setup consisting of seven Zylia 3rd order ambisonics microphones, namely one central microphones (in relation to the installation) surrounded by six microphones equally spaced around a circle with a 2-meter radius, all at ear level (1.5m from the floor) (as shown in Fig.1).

The same spatial audio recording setup was used for both installations to evaluate a practical and simple method for documentation (as opposed to tailoring the set-up to each installation).

Several recordings were made for each installation with different conditions. For JPG's work, we recorded several sessions of JPG interacting with the work and one session with a sound artist familiar with the work and also a collaborator of the project. For ES's

work we recorded eight sessions with different room acoustics conditions (the MultiMedia Room has variable acoustics) and in the presence or absence of visitors. These recordings were submitted for review to one project collaborator familiar with the artwork as well as an expert in sound art creation (a different expert for each artwork). They selected a ten-minute recording slice they considered to be best representing the work.

<FIGURE 1>

Interactive listening sessions

These spatial audio recordings were subsequently used for the next phase of the project which involved interactive listening sessions and interviews with participants in the Audio-editing Laboratory of CIRMMT. We designed a graphical user interface in Max-MSP allowing participants to interact with the spatial audio recording (see Fig. 2). It consisted in an aerial view of the installation (based on a picture for ES and a diagram for JPG) through which participants could freely move in space (x and y coordinates) as well as in time. They could record and recall up to six positions (in space and time for each installation). The GUI did not display the position of microphones to participants to avoid influencing their experience of the recording.

The interpolation of spatial audio between microphone positions was processed using Zylia MaxMSP objet, 6DoF Higher Order Ambisonics (HOA) Renderer v2.1.0. The output was rendered in binaural using SPARTA's library v1.5.0. The version of MaxMSP was v8.1.11.

<FIGURE 2>

Participants were using headphones (Sennheiser HD-280) equipped with an IMU sensor (Yost USB IMU) to feed yaw, roll and pitch values into the HOA renderer. They had control over the general level, which was not calibrated to match the real-life conditions. The virtual position in the sound installation was controlled either with a joystick or a trackpad (see Fig. 3) while standing up or sitting up, based on the participant's preference. Interpolation parameters for the HOA renderer were adjusted and validated by ear and according to the geometry of the recording setup by collaborators of the projects, with an expertise in acoustics and sound art creation, to produce a smooth transition between positions for JPG's work. However, with the limited documentation available for the different parameters (volume threshold, volume range, HOA threshold, and HOA range), we were unable to achieve a perfectly smooth transition for ES's work. We consulted with Zylia and relied on their recommended parameters, which led to audible artefacts (discussed under Limitation).

<FIGURE 3>

Participants and protocol

Due to the COVID-10 pandemic, we had limited access to museums and galleries, and difficulties in recruiting participants for an in-person study. Sixteen participants, including the two artists, ES and JPG, took part in the study between February and April 2022. They were recruited through convenience and snowball sampling based on the main expertise (described in Table 1). However, most participants reported expertise in more than one field with varying levels of experience (0 to 5 years; 5 to 10 years; 10 to 20 years; more than 20 years). Two participants are considered as having dual expertise as they reported their highest level of experience in two fields (one SA+SE and one CO+CU). We first piloted the experiment with one sound artist, whose results were included in the study as no changes were made after pilot testing.

Fields of Expertise	Main expertise	Have some knowledge
Sound Artists (SA)	6 + 2 (ES and JPG)	13
Sound Engineers (SE)	5	7
New media and Sound art Curators (CU)	4	7
New media and Sound art Conservators (CO)	1	3

Table 1. Distribution of expertise for the participants of the study

Participants started by filling out a screening questionnaire on their expertise and familiarity with the artists and each specific work. We provided a brief description of the work in case they were not familiar with it.

We then introduced the graphical interface and the functionalities for recording significant positions and encouraged them to spend as much time as needed to experience the spatial audio rendition in space and time. They could move freely in space, within a circle centered around the installation represented by the spotlight (see Fig. 2), as well as navigate in time, within the ten minutes of the recording. During this exploration, they were asked to select a minimum of three significant positions in space and in time which they considered to be interesting or important for the comprehension of the artwork.

This exploration was followed by a semi-structured interview. The interview guide was structured into 3 sections corresponding to 1) overall experience, 2) description of the significant positions, 3) implications for documentation and preservation. Section 3 focused on the distinction between tacit and explicit knowledge, and, more specifically, the notion of significant knowledge proposed by Boutard and Guastavino (2012), an extension of the notion of significant properties in the domain of digital preservation aiming at modelling the tacit-explicit dimension in documentation methods. A fourth section asked participants to categorize the work along categories developed in a previous study (Fraisie et al. 2022). However, most participants were not familiar with the terms used and we subsequently decided to exclude this section from the analysis.

The full interview guide is presented in Table 2.

Q1. Overall experience	
Q1.a	How would you describe the work?
Q1.b	What is your general sensory experience of the work?
Q1.c	What is your spatial impression of the artwork?
Q1.d	<i>[For the sound artists only]</i> Do you recognize your work in this experience?
Q2. Significant positions	
Q2. a	Why did you record this position?
Q2. b	How is this position relevant to the comprehension of the work (spatially, temporally, etc.)?
Q3. Documentation of preservation	
Q3.a	How easy (or difficult) is this experience to be transcribed in written documentation?
Q3.b	In your opinion, could the documentation of this position help the process of reinstalling the artwork and, if so, how?

Table 2. Interview guide

All participants repeated the process for both works, starting with ES’s work and finishing with JPG’s work.

The free-format descriptions of overall experience (Q1) and significant positions (Q3) were coded by the first 2 authors using a combination of inductive thematic analysis (to identify themes emerging from the qualitative data) and deductive content analysis (using themes derived from the literature). The significant positions coordinates were analyzed in relation to the main expertise of the participants and used for descriptive analysis. The questions on documentation and preservation (Q3) were coded into 3 ordinal categories, namely: 0-impossible, 1-to some extent, 2-easily for Q3.a ; and 0-No, 1-To some extent, 2-Yes for Q3.b. We decided to use open question in Q3a and Q3b section to be able to check for emerging questions regarding these topics, and while some elements participated also to the inductive part of the analysis it made the coding into ordinal categories complex and based on the interpretation of the coder, especially for the intermediary level.

Results

Overall experience

Questions on overall experience were used as an introduction to the other section and to identify general issues about the sensory experience of the art installation work in a mediated virtual environment that would have importance for documentation methodologies. When relevant, the answers were coded along with the responses of the other section. The creators of the works recognized their works in the reproduced environment (Q1.d), which served as a validation of the methodology, but also commented on limitations of the spatial rendering and the fixed media rendition of interactive installations. This is inherent to the partial presentation of the work with a document which does not intend to provide a virtual rendition as was done, for example,

by Zouhar et al. (2005), and Lombardo et al. (2009) for the Philips Pavilion at the Brussels World Fair in 1958, or Cluett and Manzione (The Museum of Modern Art 2020) for David Tudor's *Rainforest V* (variation 1).

Signification positions

Figure 4 displays all selected significant positions that were described as interesting for reinstallation purposes to some level (Q3.b value of 1 or 2). Bright colors represent the coding of high values (interesting for reinstallation) and darker colors represent the coding of lower values (to a certain extent). Each field of expertise is coded in a separate color, but we combined conservators and curators as the only conservator was also a curator. The blue circles with no filling represent the microphone positions (not displayed to the participants).

Looking at the whole range of selected positions for both works, the data seems difficult to read. There is a higher readability in the study case of ES's work that was expected as the installation is centralized in one complex object in the middle of the room.

<FIGURE 4>

For ES, we have a clear distinction between on the one hand SAs and SEs and on the other hand the CUs+COs in terms of geographical spread: CUs+CO selected position clustered around the central element while SAs and SEs selected positions throughout the listening area, including some further away from the center. This is consistent with a higher focus on the spatial image within the room, which converges with the analysis of QS1a and QS1b (see following section). We also can identify more frontal positions from SAs as compared to SEs. Lastly in terms of tacit and explicit knowledge (not represented in figure 4), SEs tend to characterize off-center positions as more complex (tacit) as opposed to the other groups. This last statement is to be taken with extreme caution as the data is scarce and relies on two mappings to ordinal scales.

For JPG, the selected positions are spread across the listening areas, which is consistent with the spread of sound sources (represented in colored square boxes with a dark blue circle on top). The control interface with the sub is located in the middle. One element that appears is a cluster around sound sources for SE profiles. Also, the influence of the graphical interface seems to appear more clearly (the selected positions are aligned with the direction of the representation of the control console), which was also acknowledged by some participants (e.g. P08 states: "Je pense que j'ai été [...] influencé par ce que je voyais. [...] je suis convaincu de tout ça [...]")¹).

Listening strategies

The qualitative analysis of the reasons for the selection of significant positions was particularly rich and revealed a wide range of listening strategies. Included in this analysis are responses from QS1a and QS1b, primarily, but also elements related to these questions but discussed during previous or subsequent questions. The selection contained positions that were deemed interesting for reinstallation as well as not interesting. The coding of the free-format responses was made as a continuous process

¹ "I think that was I saw influenced me. I am convinced of that".

by two researchers with different fields of expertise relevant to the study: soundscape research, sensory experience, preservation and conservation for art and technology, documentation of creative processes.

								Listening modes									
								Interactio n	Descriptive				Curatorial	Comprehensive

Table 3 – Summary of the qualitative analysis of listening strategies. Number of positions coded in each leaf category according to the expertise and sum for the root category.

The outcome presented in Table 3 is coded by positions rather than by participants, each case showcasing the number of positions coded in this category, but the coding was not mutually exclusive. One selected position may be coded under several categories and the sum of leaf categories can be less than its actual sum if the same position is coded in several leaf categories pertaining to the same root category. There is no ponderation by the number of participants in each category. The top categories are: *A-Method*; *B-Hedonic*; *C-Re-Presentation*; *D-Listening modes*; *E-reference position*; and *F-Presentation*.

A-Method corresponds to analytical processes developed by participants to make sense of the global soundscape. For example, a comparison of the same position at different times or different positions at the same time (not possible for the actual installation). Interestingly these strategies were primarily discussed by SA profiles and few SE profiles referred to such ideas explicitly.

B-Hedonic corresponds to positions selected for their aesthetic value and the pleasure they give to the participant. P11, a SE profile, states: “This is the position that I found to be the most pleasing and could be listened to for twelve minutes”. P09, also a SE, verbalizes it differently: “you know, like in a theater when you want to choose a particular space, a particular seat. That was my favorite seat”. As such it represents a subjective statement that may or may not be related to the selection of a position for its representativeness (as presented here below) and relates to the *Subjective listener*

experiences category in Brost's framework who adds that "[...] whether a sound is pleasant or not can depend on the listener's cultural background and personal experience".

C-Re-presentation relates to the technological setup for the study. The artwork is less important in this category and participants reflect on their involvement with the virtual rendering but also with critics of the spatial audio rendering which is further discussed here below. It relates to the document itself and how it relates to the sensory experience of the artwork itself. In terms of questioning of the spatial audio recording and rendering, it came mostly from SE profiles, for example P12 who selected a position at equal distance from 3 microphones states for JPG's work recording: "j'ai choisi cette position d'écoute-là parce qu'il y a comme une transition, [...] Je ne sais pas si c'est la captation ou si c'est la position des colonnes [...]"². The second perspective in this category, *Body & Space*, describes the ability to relate to the actual experience of the work. P14, a CU profile, justifies a position described as 'rather bizarre' like this: "j'essayais après d'avoir une expérience de mon corps dans l'espace". P14's statement brings this sub-category closer to Rumsey's (2002) notion of presence : « defined as the sense of being inside an (enclosed) space" (p. 662).

D-Listening modes is a complex category containing four subcategories. *D1-Interaction* describes the relation to the actual work considering that both installations could be triggered by the visitors when acting with the interface in the case of JPG or by producing environmental sounds in the case of ES. Several participants noticed sound elements giving an insight into the interactive nature of the work or selected a position that would be the position of a visitor interacting with the sound installation with the intention to relate to the sensory experience in this context.

D2-Descriptive presents strategies focussing on elements of the soundscape, either physically (with sound sources) or acoustically (with sound objects) or geographically (with sound areas). For the latter, one reason for the selection, for example, was the characterization of the external limit for the sound installation, defining where the visitor is entering its space sonically. SEs tended to focus on sources and areas, whereas SAs and COs+CUs provided a more mixed perspective. Most elements in this general category have been described in previous frameworks and with greater details, namely Fraisse et al. (2022) within their category *Sound design approaches*, from a sound studies perspective, or Brost (2018) within the category *Sonic parameters*, from a museum studies perspective. Still, both are constructed over the design of sound art installation rather than the sensory experience of visitors.

D3-Curatorial relates to trajectories curated by participants. In this paradigm the succession of positions is critical. As such, it relates to Brost's category *Additional listener experiences* which "describe the key listener positions and the desired listener experience", but with a narrative. This perspective was indeed proposed by a CO+CU profile, P13 who concludes that the selected position: "[...]me semble faire partie d'un parcours naturel chez le visiteur"³. P13 used the same strategy for both works. This

² "I chose this listening position because there is a transition. I don't know if it's due to the recording or if it's the position of the columns".

³ "It seems to me to be part of a natural trajectory for the visitor".

category reflects also the idea of an analysis in the form of a ‘signed listening’ as described, notably, by Donin (2004). For example, P05, a SA profile, mentions that “tous les points sont une progression du simple vers le complexe [...]”⁴.

D4-Comprehensive proposes the counterpoint to *D2-Descriptive* with a focus on emergence from the combination of sources and environment rather than specific elements. This includes questions of blend where we find positions giving a balance between the direct sound and the contribution of the room. The contribution of SE profiles in this category is noticeable, as expected. The other part of this category presents strategies that relates directly to the notion of holistic listening, in the sense of analysing the soundscape as a whole rather than individual sound sources or events. Raimbault (2006), opposed descriptive listening to holistic hearing which “processes the soundscape as a whole, without specific semantic processing of any sources” (p. 935). P-06 describes such a holistic listening strategy to the overall work throughout space and time, while relating it to the next category that we will detail: “c’est un moment assez représentatif de l’œuvre et de l’espace. Oui, mais dans son ensemble”⁵.

E-Reference position describes positions that are considered specifically relevant for the understanding of the work in terms of spatial audio, whether for quality of the spatial image, or its representativeness of the work as a whole.

The notion of *Quality of the spatial image* has received significant research attention in relation to the evaluation of spatial audio reproduction. Guastavino and Katz (2004) identified readability as an important criteria related to the definition of the spatial image and ability to comprehend a complex auditory scene. While the task of participants was not to evaluate the reproduction, the analysis of their verbalizations points at these concepts. Here, the quality of the spatial image category relates to readability and to the ability to hear depth or different layers. Both are exemplified in P-00’s statement: “but here there’s more of a layer involved, or layers, and the atmosphere that it creates is more spatial somehow, there’s more things going on, all around, which are very interesting, it’s interesting to be there and try to focus on all the different details”.

Representativeness is a category that showcases the idea of the work and may be compared to Brost’s (2018) somehow converging category labelled *ideal listener experience* which “describe the artist’s ideal listener experience of the work (orientation and movement of the listener; location, direction, sound intensity/levels, presence or absence of low-frequency vibration, etc.)”. Brost, echoing our research objectives, mentions also that “if the artist works closely with a sound professional, ask that person to describe this as well”. This category includes both the representative positions themselves – “I think that’s how the composer wanted people to experience this piece” says SE profile P01 – as well as references to impossible positions which may or may not be representative. Artist ES exemplified this by selecting an “impossible” position for her own work (on top of the installation, which is not accessible in the physical space) and describing it as ‘almost perfect’. Representativeness is discussed in relation to both space and time. P13 a CO+CU profile, as well as P02, a SA profile with a familiarity with the work, associate the significance of their selection to the distinction between a passive position (for the former) and an active position (for the latter).

⁴ “All positions are a progression from simple to complex”.

⁵ “This moment is quite representative of the work and the space. Yes, but as a whole”.

F-Presentation refers to everything that is dependent on the exhibition context and the sound art installation as an instance. It relates to the idea of identity versus iteration discussed by Brost's (2018) based on the definition of the terms by Philipps' (2015). While the distinction between identity and iteration was of particular importance in JPG's case – the artist redesigned the control mechanisms because of the pandemic context so that only feet were used – participants could relate to this distinction mainly in relation to a few factors that they identified in their strategies. The first one is room acoustics and its relevance or relation to the work. In this category the focus is on the spatial attributes of the room itself rather than the spatial attributes of the auditory scene within the room (as described by Rumsey 2002). As Kelly (2011) reminds us, “a continuing concern to curators of sound in contemporary art is the space of the gallery itself” (p. 17). P14, a CU profile, for example, questioned the acoustics of the exhibition room for JPG's work: “jusqu'où peut aller cette réverbération-là dans l'œuvre, jusqu'où on se permet d'aller, parce que des fois ça peut être un choix de l'artiste aussi”, a statement that resonates with the limitations expressed by JPG in his own interview for this specific exhibition context. This subcategory is indeed well represented in all fields of expertise in Table 3. The top category relates also to external sounds sources emerging from the recording that participants considered as significant. contextualize the artwork, such as traffic noise. P06, a SA profile, mentions traffic noise this way: “C'est comme un élément parasite qui est là, mais qui nous met en contexte plus; on a plus l'impression d'être dans un espace”, which also relates to the *re-presentation* category. The last categorial element pertaining to this main category is the complementary choice, in relation to room acoustics, of positions selected for minimizing this context (typically, close to the sound sources) and as such relates more to the identity of the artwork, as least in sensory experience terms. Relation between categories and position Because of the relatively small amount of data and the large number of categories emerging from the qualitative analysis, it is difficult to extract information from the conflation between the quantitative and the qualitative data. We will show here an example of triangulation to emphasize the tool methodologically and its potential for targeting in the future specific categories to extend the research. Figure 5 displays the positions selected for the category *Representativeness* for both works according to the field of expertise.

<FIGURE 5>

Discussion

This first outcome of the analysis is the impressive variety of listening strategies that participants used during the data collection, which touches on the conceptual frameworks from the different fields of expertise discussed in this study. While there are tendencies in terms of strategies, the crossover established in table 3 is clear (we have to take into account the limitations discussed here below), with some interesting takeaways, like the preference for the global panel of *comprehensive* strategies for SE profiles as opposed to analytic *methods* for SA profiles, and the expected focus on *sources* and *sound object* by CU+CO profiles (which is consistent with Brost's framework). The development of narratives in what we have labelled *curatorial*

strategies for all fields of expertise is also interesting in terms of the many ways to create them and could certainly be developed further in terms of research. While a statement to take with caution (see here above), in terms of significant knowledge, the tendency by participants to characterize differently what they consider easier to verbalize in relation to their sensory experience, according to their field of expertise, motivates us to push further this part of the research with an operationalization of the tacit-explicit dimension that fits a more descriptive inquiry and a focus on several categories. But the diversity of responses to this question from respondents is already an insight into the noteworthiness of this dimension.

Several limitations are part of this study. First, we chose to focus on the auditory immersive experience using a fixed media rendition, thus failing to account for the interactive dimension of the installations. This allowed us to focus on our object of study, namely the document rather than the sound art installation, and to confront our findings to Brost's framework which is primarily defining sound elements and sound-related elements in the documentation. In the same vein, we chose to use a generic recording protocol, along a predefined array of equally spaced microphones, instead of tailoring the process to fit each work. The rationale was to rely on a pragmatic position to investigate the extent to which we can use simple tools to discuss long term documentation for sound art installations. By doing so, we also consider that 6DoF spatial audio recordings in the context of documentation would be more of a methodological tool rather than a direct documentation tool, which is consistent with the volume of data to preserve if it were to be the latter, especially at a time where digital archiving community are more and more discussing the environmental impact of digital preservation.

The interpolation between recording positions, especially in the case of Estelle's work, had an impact on the spatial audio features of the rendering, which was acknowledged by several participants and had an impact on the selection of significant positions. The unexpected outcome of this situation is the ability to relate this shortcoming to the documentation principles, especially if we discuss in terms of *identity* and *iteration*, or in Brost's terms *Sonic Identity* and *Installation documentation*, by emphasizing what is not a part of the work rather than what is, in the same vein as discussed for room acoustics. Furthermore, in terms of expertise, it should be noted that most participants at least some level of expertise outside of their primary field, so the analysis by expertise should be interpreted with caution. These limitations arose in the context of an exploratory research project trying to carve new research directions in the documentation of sound installation works.

We have made several references to Brost's framework during the analysis, whether in relation to her inclusion of broad categories relating to listener experience or the specification of sound sources and events. Taking a sensory experience perspective on documentation, we still observe converging categories from our analysis, making clear the potential articulation between both frameworks and the possibility to better specify and define more systematically the elements of listener experience that she proposes. In our opinion, this would require relating the sensory experience and the constituent listening strategies to the elements of documentation themselves rather than defining them as independent categories.

Further research could be conducted by focusing on specific categories and investigating the relevant strategies for each field of expertise. In this study we have used spatial audio recording as a data collection instrument, but this research has now the potential to be extended to multi-expertise collaborative work and to investigate such tools in the context of more ecologically valid tasks relating to the specification of documentation for sound art installation.

Conclusion

Documentation of sound art installations is an interdisciplinary endeavor. Brost (2018) made it explicit by stating that “for time-based media works that foreground sound, conservators must be conversant with sound physics, acoustics, audio engineering and sound design so that they can have productive conversations with artists and sound professionals in order to create meaningful documentation of the significant aural properties of an artwork for the future”. From this study, the potential for operationalizing this interdisciplinary framework started to emerge with the goal to make documentation procedures better formalized in relation to each field of expertise regarding the sensory experience.

As mentioned before, we do not advocate for the use of 6DoF spatial audio recordings as a primary document about the work but rather as a mediation for the specification of documentation methods with all stakeholders. The fact that we have a broad range of shared strategies to document the sensory experience across fields of expertise with different focuses outlines the potential to use minimal spatial audio recordings tools, such as the ones we used in this study, for this purpose.

While on the one hand sound artists have their own documentation methods, and in some cases dedicated professionals, and on the other hand museums have their documentation frameworks, this study is positioned within a broader perspective which promotes the design of comprehensive frameworks bridging practices and expertise. In this context, we have proposed to use spatial audio recording as a mediation for discussing, improving, converging on the topic of sound art installation documentation between stakeholders.

Acknowledgments

We would like to thank the [Social Sciences and Humanities Research Council](#) of Canada for funding the SAD-SASK project, Gabriel Lavoie Viau for developing the interface, Jack Kelly and Florian Grond for the recordings, Julien Boissinot and Yves Methot at CIRMMT for their support in the laboratory. We would like also to thank our collaborators for the discussions and guidance: Nicolas Bernier, Seth Cluett, Patricia Falcão, Philippe-Aubert Gauthier, and Jack McConchie.
